

1. **A brief discussion of how you have implemented the STP protocol. Provide a list of features that you have successfully implemented. In case you have not been able to get certain features of STP working, you should also mention that in your report.**

| Sender features | Receiver features |
|-------------------------------------|-------------------------------------|
| Three-way-handshake | Three-way-handshake |
| Four-segment connection termination | Four-segment connection termination |
| SEQ and ACK numbers | SEQ and ACK numbers |
| MSS and MWS | Checksum |
| PLD module | Reorder segments |
| Timeout operation | Write log |
| Fast retransmission | |
| Write log | |

I write some utility function first such as the encode and decode function to transform data, also do the checksum; the log function in both sender and receiver to write log and count different kinds of segments.

After preparation, I implement the three-way handshake to set up connection and then hold this state and wait for data transmitting. When the whole transmission is finished, sender and receiver terminate connection by finishing four-segment handwave.

Sender has a left-right organism to control retransmission. The left represents being ACK one, right represents send one. The left always catch up with the right until they are the same value. It also means the length of data is 0.

The sender sends several segments at one time and wait for ACKs. When the flag is not finished, the segment that sender send go through PLD module. If the random float is smaller than pDrop etc., then execute corresponding operation. For example, if corrupt occurred, the first bit of payload will be modified then receiver will check the checksum in header and discord it. If timeout happened, sender will resend that package in a new window, following other packs together.

There is a buffer in receiver that aimed to reorder the segments duplicated or out of order due to pOrder or retransmission. First reorder segments by their sequence number. If there are more than one segment and it is a duplicated segment, then pop it out of buffer. If the sequence number is next to other segments, then combine then and pop the original one.

2. **A detailed diagram of your STP header and a quick explanation of all fields (similar to the diagrams that we have used in the lectures to understand TCP/UDP headers).**

| | | |
|-----------|--------|------------------------------------|
| DATA_LEN | 4 byte | The length of data. |
| SEQ_NUM | 4 byte | The sequence number. |
| ACK_NUM | 4 byte | The acknowledge number. |
| FLAG | 2 byte | Flag field, SYN, ACK or FIN |
| CHECK_SUM | 2 byte | Check segment is corrupted or not. |
| DATA | n byte | Data, the payload of segment. |

3. **Discuss any design trade-offs considered and made. Describe possible improvements and extensions to your program and indicate how you could realize them.**

In the PLD module, the original of retransmission I designed was: if the counter of ACK DUP is more than 3, then reset the counter to zero and retransmit the segment. It may lead to retransmit the same segment for several times constantly and consume tremendous running time. So, I finally set only retransmitting segment for one time, maybe it could not fit the specification perfectly but could save lot of running time.

4. **Indicate any segments of code that you have borrowed from the Web or other books.**

All my code for this assignment is original, there is nothing from Web or other books.

5. Answer the following questions: (include any output as an appendix to the main report.pdf, appendix is not included in the 5-page limit)

- a) It easily to indicate where dropping occurred. Focus on sequence numbers, if it suddenly jumps a gap with the size of MSS, there must be a drooping occurred.

```
rcv          0.01    D          101          100          1
snd          0.01    A           1           0         201
rcv          0.01    D          301          100          1
```

Like the figure 1 in appendix shows, the sequence number suddenly jump from 101 to 301 without 201, it means the segment with sequence number 201 has been dropped and will be retransmitted later (sequence number 201 between 601 and 701).

```
*****
snd/DA       0.01    A           1           0         201
rcv          0.01    D          601          100          1
snd/DA       0.01    A           1           0         201
rcv          0.02    D          201          100          1
snd          0.02    A           1           0         701
rcv          0.03    D          701          100          1
```

According to figure 1 and figure 2, there are 4 drops and 24 drops separately in cases with pDrop = 0.1 and pDrop = 0.3

- b) When gamma = 4, the segments transmitted and running time significantly decrease, because as the gamma increases, the timeout interval increases. Because random generated delay is more likely shorter than timeout interval, there will be less segments retransmitted due to timeout. However, when gamma = 6, segments transmitted and running time are similar with the case with gamma = 4. The reason is the increase of timeout interval is big enough and would not have too much influence. (Not sure)

| | Segments transmitted | Running time |
|-----------|----------------------|--------------|
| Gamma = 2 | 1201109 | 105.91 |
| Gamma = 4 | 754141 | 69.02 |
| Gamma = 6 | 759421 | 68.97 |

- c) The file has been successfully transferred. The overall transfer took about 7 minutes. The pDrop may be contribute to running time most. First, segments dropped are more than the other three kind of segments. Second, the sender will retransmission constantly until receive ACK, while pDuplicate and pOrder only need to reorder at the receiver. Finally, pCorrupt is similar with pDrop, it also contributes to running time much.

So, I conclude pDrop is the most critical contributing most in the overall transfer time.

6. Appendix
